6231. PHYSIOLOGICAL BASES FOR EXPERIMENTAL AND CLINICAL LYMPHOGRAPHY - Physiologische Grundlagen der experimentellen und klinischen Lymphographie - Málek P. and Kolc J. Inst. für Klin. und Exp. Chir., Prag - ZBL.CHR. 1958, 83/26 (1303-1317) Illus. 13
In experimental animals the problem of radiolymphography was studied from the viewpoint of the physiological properties of the lymphatic system. Direct and indirect lymphography were studied and 3 types of contrast medium were used: colloidal, crystalloid and iodized oil. In direct lymphography it was proved that the speed of the removal of the crystalloid contrast medium from the lymphatic system is primarily influenced by the condition of the blood capillaries. The speed of the removal of the colloidal contrast medium shows the real transport and maintenance function of the lymphatic system. The speed with which crystalloid contrast media are removed can be considerably limited by the use of adrenaline. In shock also the crystalloid substance remains considerably longer in the lymphatic system. In indirect lymphography with colloidal substances (thorium dioxide sol) a distinction should be drawn between the 'early' and 'late' lymphogram. Indirect lymphography can also be performed with a crystalloid substance, when adrenaline is injected at the same time. The 'functional lymphography' is recommended in which first a crystalloid and next a colloidal contrast medium are applied. (IX, 14)

Title : Antibiotics with Directel Fenetration into the Lymphatic System.

Orig Pub: Antibiotiki, 1958, 3, No. 1, 45-51

Abstract: Antibiolymphins (I) are salts of antibiotics with high-molecular-weight substances. The salts of streptomycin and neomycin with polymentacrylic acid, with dextran sulfate and carboxymethyl-starch were tested. They are absorbed in intramuscular introduction to a considerable degree by means of the lymphatic system. As compared with commonly used antibiotics, they create lower concentrations of antibiotics in the blood and cir-

Title : Problem of the Tolerance of Microorganisms to
antibiotics in Surgery.

Orig Pub: Rozhl. chirurg., 1957, 36, No 1, 21-31.

Abstract: The authors cite basic data on the appearance of tolerance of microorganisms based on their own observations and those in the literature. It is emphasized that antibiotics, on the one hand cause the development of tolerance of microorganisms, and on the other, impair the biological equilibrium of the organism, making it susceptible to secondary infections. -- From the authors' resume.

duced from 30 min. in the normal state to 3-6 min. in shock. This effect was explained by increased vascular permeability and was used as an index of depth of shock. In contradistinction to this effect it was already known and frequently described that resorption from the tissues and from the gastrointestinal tract during shock is diminished. In this paper this discrepancy is demonstrated experimentally and explained by the different resorption of haemotropic and lymphotropic substances in the organism. Inulin and radioactive phosphorus are resorbed more slowly during shock than are dextran, Congo red and suspensions of bacteria such as *B. perfringens*, which materials are resorbed by lymphatic route into the general circulation. In shock the lymphatic barrier is rendered non-functional, resulting in massive toxæmia of the organism. Such occurrence is well seen in the clinical picture of oedema malignum, where there is lowered general resistance. Resorption by the lymphatic route is enhanced in shock and this route has been used with success by the author for procaine penicillin, which is absorbed from the tissues as rapidly as the soluble penicillin G.

Study of the dynamics of the circulation of substances in organisms during states of shock CAS. LÉK. ČES. 1956, 95/17 (449-454) Graphs 9 Tables 3 From the viewpoint of the known dissociation of absorption of haematotropic and lymphotropic substances during shock, the resorption of penicillin was investigated during tourniquet shock after i.m. injection. It was shown that the rule of dissociation of absorption had its consequence in the absorption of various kinds of penicillin. The potassium salt of crystalline penicillin G behaves as a haematotropic substance and the procaine salt as predominantly lymphotropic. It was found that the procaine salt of penicillin as a considerably lymphotropic substance, penetrates during shock into the lymph faster and more powerfully. By means of the procaine salt of penicillin in experimental animals, the blood concentrations of antibiotics, which mostly exceed the values obtained in animals without shock, are safely effective from the beginning. When the potassium salt of crystalline penicillin G is applied there can be no reliance on the quick achievement of effective concentrations which are mostly substantially lower under shock. The practical consequences of this experience are referred to with emphasis on the 'lymphatic blockade' under shock.

4537. (953) MÁLEK P. Inst. für Klin. und Exp. Chir., Prag. *Experimentalstudie auf Grund neuer Erkenntnisse über die Absorption von Stoffen in Schockzuständen. Die Absorption von Penicillin. Experimental study based on new data regarding the absorption of substances in conditions of shock. The absorption of penicillin ZBL.CHIR. 1956, 81/43 (2255-2262) Graphs 6

- (1) The absorption of penicillin in rabbits in tourniquet shock after intramuscular injection was studied on the basis of the knowledge on the dissociation of the absorption of haemotropic and lymphotropic substances during shock. (2) It was proved that the law of the dissociation of the absorption has a consequence in the absorption of various kinds of penicillin. Potassium salt of crystalline penicillin G behaves like a haemotropic, and procaine salt like a predominantly lymphotropic substance. (3) It was found that penicillin-procaine salt, being a substance with considerable lymphotropic properties, penetrates quicker and more intensely into the lymph during shock. (4) In animal experiments, penicillin-procaine salt produced, from the very beginning, reliably active concentrations of antibiotics in the blood, which usually were higher than those in animals without shock. (5) In the application of the potassium salt of crystallized penicillin G, the rapid production of active concentrations, which are usually considerably lower in shock, cannot be relied upon. (6) Practical conclusions of the findings are mentioned and the efficacy of 'lymphatic block' in shock is stressed.

Title : Investigation of the Dynamics of Circulation of Substances
in the Body in the State of Shock. III. Absorbtion of
Penicillin in Turniquet Shock.

Orig Pub : Casop. lekaru ceskych, 1956, No 17, 449-454

Abstract : In turniquet shock in rabbits the absorbtion of intramuscularly administered potassium salt of Penicillin (I) and procaine Penicillin (II) was studied. I penetrates more rapidly the blood stream, and II into - the lymphs. In the administration of the procaine salts into the blood a higher concentration is formed, as compared with the control healthy rabbits, and the administration of potassium salts - a much lower concentration.

Vliv sera myastheniku na nervosvalovy preparat zabi Research on the pathogenesis of myasthenia and myotonia with regard to treatment. experimental part. I. The influence of the myasthenic serum on the neuromuscular preparation of frog Cas. lek. ces. 1951, 90/34 (1011-1014) Graphs 1 Tables 1 Illus. 2 The authors elaborated a method for the determination of the active factor in the blood of myasthenics. This factor augments in a striking was the muscular fatigability, studied on the neuromuscular preparation of the frog. In the registration of the isometric contractions of the neuromuscular preparation of frogs injected with serum of myasthenics, they found characteristic changes when compared with registrations of frogs injected with normal serum. A striking diminution of the muscular effect was found in registrations made on the same neuromuscular preparations after a rest. Examinations of and comments on 4 cases of myasthenia gravis pseudo-paralytica are given. In the repeated examination, the results are convincing. This method may be used in investigating the aetiology of myasthenia and myotonia and in the evaluation of the treatment of both diseases.

"Prolonged Persistence of Tetracycline Antibiotics in the Organism under Pathological Conditions"

Prague, Casopis Lekaru Ceskych, Vol CII, No 32/33, 16 August 1963, pp 902-906.

Abstract [Authors' English summary, modified]: Discussed is the prolonged fixation of tetracycline antibiotics (TA) under pathological conditions. Under physiological conditions the TA are retained only in biologically active bone marrow. Under pathological conditions prolonged fluorescence is found also in tissues liable to calcification. A very intensive trapping and retention occurs in the striated skeletal and cardiac muscles. After discussing various specific cases the authors conclude that the fixation is caused by the formation of stable chelate TA complexes in tissues with bivalent cations, particularly cations of calcium. This phenomenon is discussed from the morphological view point. Forty-two references, including 25 Czech.

TITLE: Results of several years of service of the NA-SKODA digital control system

SOURCE: Automatizace, no. 8, 1965, 211-212

TOPIC TAGS: computer control system, production engineering

ABSTRACT: The article describes the experience with the NA-SKODA Digital Control System at the V. I. Lenin Plants and states that it shows that the processing of shaped parts in large lots is economical; so far, however, the production of a small quantity of parts has been expensive. Moreover, the designers have hesitated to select challenging forms and have selected more ordinary, very simple forms because of the presence of the system. Orig. art. has: 3 figures. [JPRS]

Title : Capacitive Generators and Their Application as a Source of High
Voltage for Ion Accelerators

Original

Periodical : Elektrotechn. obzor, 1956, 45, No 3, 138-144 (Czech; resumes
in Russian, French, and English)

Abstract : The possibilities are considered of obtaining a high voltage with the
aid of capacitive generators. These generators operate on the principle
of the variable capacitor. Unlike the Tepler generators, the ca-
pacitive generators are provided with an exciting armature, making it
possible to connect them in stages to obtain very high voltages. A
2-stage generator was constructed and used to verify the principle of
the cascade connection, and the characteristics were plotted. Direc-
tions are given for the construction of a machine of very high voltage;
the shortcomings of the capacitive principle are described and methods
indicated for eliminating these shortcomings.

"Present-Day Problems in the Investigation of Periodic Functions in Living Organisms"

Prague, Ceskoslovenska Fysiologie, Vol 15, No 3, May 66, pp 228-239

Abstract: Exogenous and endogenous periodicities and rhythms are discussed. Synchronizing factors and changes in daily rhythms are described. Damage to endocrine organs due to constant light or darkness is discussed. Rhythms important in medicine in diagnosis, therapy and disease prevention are described. Influence of cycles and rhythms in the reproduction of animal and vegetable life is evaluated. The influence of periods, cycles, and rhythms on extraterrestrial life is discussed. 12 Figures, 36 Western, 4 Czech, 1 Russian reference. (Manuscript received 31 Aug 65).
